

Appendix for Strong Leader, Fragile Party: How Even a Weak Party Can Protect a Powerful Leader?

Takuya Furusawa

Proof of Lemma 1

Suppose that the leader does not build a party and deduces the elite's optimal strategy with backward induction. Let V_E denote the elite's utility in Period 2;

$$V_E(\text{reject}) = (\sigma + b)p_2 + k(p_2)(1 - p_2),$$

$$V_E(\text{accept}) = x_2.$$

The leader can prevent the elites from rebelling iff

$$\begin{aligned} V_E(\text{accept}) &\geq V_E(\text{reject}) \\ x_2 &> (\sigma + b)p_2 + k(p_2)(1 - p_2) \equiv x_2^* \end{aligned}$$

which implies that the incumbent has to offer x_2^* to deter the elite if she deems it preferable. Given the assumption $x_2 < 1$, this is possible if and only if

$$(\sigma + b)p_2 + k(p_2)(1 - p_2) - 1 \leq 0$$

Let $\phi_2(p_2, k(p_2))$ denote the left-hand side. Differentiating this function, we have

$$\frac{d\phi_2(p_2, k(p_2))}{dp_2} = (\sigma + b) + k'(p_2) - k(p_2) - p_2k'(p_2) = \sigma + b - k(p_2) + (1 - p_2)k'(p_2)$$

$$\frac{d^2\phi_2(p_2, k(p_2))}{dp_2 dp_2} = -k'(p_2) + k''(p_2) - k'(p_2) - p_2k''(p_2) = -2k'(p_2) + (1 - p_2)k''(p_2) < 0$$

The last inequation is derived from the assumptions $k'(p_2) > 0$ and $k''(p_2) < 0$.

Since $\frac{d\phi_2(p_2, k(p_2))}{dp_2}$ decreases in p_2 ,

$$\min_{p_2 \in [0,1]} \frac{d\phi_2(p_2, k(p_2))}{dp_2} = \frac{d\phi_2(p_2, k(p_2))}{dp_2} \Big|_{p_2=1} = \sigma + b - \bar{k} > 0 \quad (1)$$

Inequation (1) is drawn from $\lim_{p_t \rightarrow 1} k(p_t) = \bar{k} < 1$, which implies $\phi_2(p_2)$ increases in p_2 .

$$\min_{p_2 \in [0,1]} \phi_2(p_2, k(p_2)) = \phi_2(0, k(0)) = -1$$

$$\max_{p_2 \in [0,1]} \phi_2(p_2, k(p_2)) = \phi_2(1, k(1)) = \sigma + b - 1 > 0$$

This means that the equation $\phi_2(p_2, k(p_2)) = 0$ has a unique solution in the interval $p_2 \in (0,1)$.

Let's denote the solution as \hat{p}_2 so that

$$\Phi_2(\hat{p}_2, k(\hat{p}_2)) = 0.$$

\hat{p}_2 is considered the solution of

$$(\sigma + b)p_2 + k(p_2)(1 - p_2) - 1 = 0 \quad (2)$$

Proof of Lemma 2

If $p_2 \geq \hat{p}_2$, then the leader abandons accommodation and offers nothing ($x_2 = 0$). Regardless, the elite accepts the same payoff, $V_E = x_2^* = (b + \sigma)p_2 + k(p_2)$.

In the same way, we can specify the condition for peaceful bargaining in period 1.

$$U_E(\text{reject}) = 2[(b + \sigma)p_1 + k(p_1)(1 - p_1)],$$

$$U_E(\text{accept}) = x_1 + (\sigma + b)p_2 + k(p_2)(1 - p_2).$$

$$U_E(\text{accept}) \geq U_E(\text{reject})$$

$$x_1 \geq 2[(b + \sigma)p_1 + k(p_1)(1 - p_1)] - (b + \sigma)p_2 - k(p_2)(1 - p_2) \equiv x_1^*$$

Given $x_1 \leq 1$,

$$2[(b + \sigma)p_1 + k(p_1)(1 - p_1)] - (b + \sigma)p_2 - k(p_2)(1 - p_2) < 0$$

Denote the left-hand side as $\Phi_1(p_1, k(p_1))$. Differentiating this function, we have

$$\begin{aligned} \frac{d\Phi_1(p_1, k(p_1))}{dp_1} &= 2(\sigma + b) + 2k'(p_1) - 2k(p_1) - 2p_1k'(p_1) \\ &= 2(\sigma + b) + 2(1 - p_1)k'(p_1) - 2k(p_1) \end{aligned}$$

$$\begin{aligned} \frac{d^2\Phi_1(p_1, k(p_1))}{dp_1 dp_1} &= 2k''(p_1) - 2k'(p_1) - 2k'(p_1) - 2p_1k''(p_1) = -4k'(p_1) + 2(1 - p_1)k''(p_1) \\ &< 0 \end{aligned}$$

The latter inequation implies that $\frac{d\Phi_1(p_1, k(p_1))}{dp_1}$ decreases in p_1 .

$$\min_{p_1 \in [0,1]} \frac{d\Phi_1(p_1, k(p_1))}{dp_1} = \frac{d\Phi_1(p_1, k(p_1))}{dp_1} \Big|_{p_1=1} = 2(\sigma + b) - 2\bar{k} > 0,$$

which implies $\frac{d\Phi_1(p_1, k(p_1))}{dp_1} > 0$ for all $p_1 \in [0,1]$. Since the function $\Phi_1(p_1, k(p_1))$ strictly increases in $p_1 \in [0,1]$,

$$\min_{p_1 \in [0,1]} \Phi_1(p_1, k(p_1)) = \Phi_1(0, k(0)) = -V^E(p_2) - 1 < 0$$

$$\max_{p_1 \in [0,1]} \Phi_1(p_1, k(p_1)) = \Phi_1(1, k(1)) = 2(\sigma + b) - V^E(p_2) - 1 > 0$$

That means the equation $\phi_1(p_1, k(p_1)) = 0$ has a unique solution in the interval $p_1 \in [0,1]$. Let's denote the solution as \hat{p}_1 , which means

$$\phi_1(\hat{p}_1, k(\hat{p}_1)) = 0$$

Since the function ϕ_1 contains p_2 , the threshold \hat{p}_1 can be considered a function of p_2 , $\hat{p}_1(p_2)$.

Implicit differentiation of $\phi_1(\hat{p}_1(p_2), k(\hat{p}_1(p_2))) = 0$ shows:

$$\begin{aligned} \frac{d}{dp_2} 2(\sigma + b)\hat{p}_1(p_2) + 2k(\hat{p}_1(p_2))(1 - \hat{p}_1(p_2)) - V^E(p_2) - 1 &= 0 \\ 2(\sigma + b) \frac{\partial \hat{p}_1(p_2)}{\partial p_2} + 2 \frac{\partial k(\hat{p}_1(p_2))}{\partial \hat{p}_1(p_2)} \frac{\partial \hat{p}_1(p_2)}{\partial p_2} - 2 \left[\hat{p}_1(p_2) \frac{\partial k(\hat{p}_1(p_2))}{\partial \hat{p}_1(p_2)} + k(\hat{p}_1(p_2)) \right] - (\sigma + b) \\ - \frac{\partial k(p_2)}{\partial p_2} &= 0 \\ \frac{\partial \hat{p}_1(p_2)}{\partial p_2} &= \frac{2 \left[\hat{p}_1(p_2) \frac{\partial k(\hat{p}_1(p_2))}{\partial \hat{p}_1(p_2)} + k(\hat{p}_1(p_2)) \right] + (\sigma + b) + \frac{\partial k(p_2)}{\partial p_2}}{2 \left[(\sigma + b) + \frac{\partial k(\hat{p}_1(p_2))}{\partial \hat{p}_1(p_2)} \right]} > 0 \end{aligned}$$

Proof of Proposition 3

In Period 2, the leader decides whether to buy off the elite with x_2^* , or to discard him by offering nothing. Her payoffs are the following:

$$V_2^R(x_2 = 0) = (1 - p_2)[\sigma + b - k(p_2)],$$

$$V_2^R(x_2 = x_2^*) = 1 + b - x_2^* = 1 + b - (\sigma + b)p_2 - k(p_2)(1 - p_2).$$

In order to derive the condition for the ruler to deter the elite, we have her gain from deterrence:

$$\begin{aligned} V^R(x_2 = x_2^*) - V^R(x_2 = 0) &= 1 + b - (\sigma + b)p_2 - k(p_2)(1 - p_2) - (1 - p_2)[\sigma + b - k(p_2)] \\ &= 1 - \sigma > 0, \end{aligned}$$

which always holds, so that the leader always prefers to deter the elite as long as it is possible.

The leader's utility in Period 1 depends on whether Period 2 allows accommodation between the two players. Let us compare the ruler's payoff in each case. First, if the elite in Period 2 is not deterrable, and the ruler opts for deterrence in Period 1, her payoff is:

$$U^R(x_1 = x_1^*, x_2 = 0) = (1 + b - x_1^*) + (1 - p_2)[(\sigma + b) - k(p_2)] \quad (4)$$

Second, if the ruler is resolved to fight the elite in Period 1, her payoff is:

$$U^R(x_1 = 0) = 2(1 - p_1)[(\sigma + b) - k(p_1)] \quad (5)$$

Third, suppose that the elite in Period 2 is deterrable. If the ruler opts for deterrence in Period 1, her payoff is:

$$U^R(x_1 = x_1^*, x_2 = x_2^*) = (1 + b - x_1^*) + (1 + b - x_2^*) \quad (6)$$

The comparison between (4) and (5) asks whether the ruler prefers to deter the elite in Period 1 when they are destined to fight against each other in Period 2.

$$\begin{aligned} U^R(x_1 = x_1^*, x_2 = 0) - U^R(x_1 = 0) &= 1 - \sigma > 0 \\ U^R(x_1 = x_1^*, x_2 = x_2^*) - U^R(x_1 = 0) &= 2 - 2\sigma > 0 \end{aligned}$$

Proof of Proposition 4

Given $p_2 + g \in [0,1]$, the threshold is the solution of the following equation:

$$\phi_1(p_1, k(p_1), p_2 = 1) = 2(\sigma + b)p_1 + 2k(p_1)(1 - p_1) - V^E(p_2 = 1) - 1 = 0 \quad (7)$$

It follows from the same logic of Proposition 2 that this equation has a unique solution within the interval $p_1 \in [0,1]$. Denote this solution as \bar{p}_1 .

The condition for self-destructive party building occurring is

$$\begin{aligned} \phi_1(p_1, k(p_1), p_2 = \hat{p}_2) &= 2(\sigma + b)p_1 + 2k(p_1)(1 - p_1) - V^E(\hat{p}_2) - 1 > 0 \\ (\sigma + b)p_1 + k(p_1)(1 - p_1) - 1 &> 0 \\ p_1 &> \hat{p}_2 \end{aligned}$$

Proof of Proposition 5

First, recall that \hat{p}_1 is the solution of Equation (3).

$$\phi_1(p_1 = \hat{p}_2, k(p_1 = \hat{p}_2), p_2) = 2(\sigma + b)\hat{p}_2 + 2k(\hat{p}_2)(1 - \hat{p}_2) - V^E(p_2) - 1 = 1 - V^E(p_2)$$

The second equation follows from the fact that \hat{p}_2 is the solution of Equation (3). Thus, the relationship between \hat{p}_1 depends on the sign of $1 - V^E(p_2)$. If $1 - V^E(p_2) > 0$, then

$$\phi_1(p_1 = \hat{p}_2, k(p_1 = \hat{p}_2), p_2) > \phi_1(p_1 = \hat{p}_1, k(p_1 = \hat{p}_1), p_2)$$

Given that the function $\phi_1(p_1, k(p_1), p_2)$ increases in p_1 , the above inequation implies

$$\hat{p}_1 < \hat{p}_2$$

In the same way, if $1 - V^E(p_2) \leq 0$,

$$\hat{p}_1 \geq \hat{p}_2$$

Next, recall that \bar{p}_1 is the solution of Equation (7) and $\phi_1(p_1, k(p_1), p_2 = 1)$ strictly increases in p_1 . Since $V^E(p_2 = 1) = \sigma + b$,

$$\begin{aligned} \phi_1(p_1 = \hat{p}_2, k(p_1 = \hat{p}_2), p_2 = 1) &= 2(\sigma + b)\hat{p}_2 + 2k(\hat{p}_2)(1 - \hat{p}_2) - (\sigma + b) - 1 = 1 - (\sigma + b) \\ &< 0 \end{aligned}$$

Thus,

$$\phi_1(p_1 = \hat{p}_2, k(p_1 = \hat{p}_2), p_2 = 1) < \phi_1(p_1 = \bar{p}_1, k(p_1 = \bar{p}_1), p_2 = 1)$$

Given that the function $\phi_1(p_1, k(p_1), p_2 = 1)$ increases in p_1 , the above inequation implies

$$\hat{p}_2 < \bar{p}_1$$

Proposition 6

Effect of k on thresholds.

Recall that \bar{p}_1 is the solution of Equation (7). In the same way of Proposition 5, let's ignore that $k(p_1)$ is the function of p_1 and assume that $k(p_1)$ is determined exogenously.

$$2(\sigma + b)\bar{p}_1 + 2k_{\bar{p}_1}(1 - \bar{p}_1) - (\sigma + b) - 1 = 0$$

By implicit differentiation,

$$\frac{\partial \bar{p}_1}{\partial k_{\bar{p}_1}} = \frac{\bar{p}_1 - 1}{b + \sigma - 1} < 0$$

Again, recall that \hat{p}_2 is the solution of Equation (2). Suppose

$$(\sigma + b)\hat{p}_2 + k_{\hat{p}_2}(1 - \hat{p}_2) - 1 = 0$$

$$\frac{\partial \hat{p}_2}{\partial k_{\hat{p}_2}} = \frac{\hat{p}_2 - 1}{b + \sigma - 1} < 0$$

Thus, \bar{p}_1 and \hat{p}_2 decreases as k increases.
